Fig. 1 Experimental design and psychophysical evaluation of spatiotemporal modulation patterns. a, Schematic of the experimental setup. Participants were seated with their hand positioned on a hollow foam board over the ultrasound phased array, wearing active noise-canceling headphones playing white noise to eliminate acoustic cues. **b**, Detailed view of the hand-device interface showing the acoustic window and focal alignment. **c**, Illustration of the five modulation patterns (DLM_2, DLM_3, ULM_L, LM_L, LM_C) and the two-alternative forced choice (2-AFC) protocol. The experiment consisted of two counterbalanced blocks evaluating intensity perception and spatial clarity. **d**, Psychophysical results ($n = 26$). Left and Center: Relative preference scores (log-odds) for intensity and spatial clarity derived from a Bayesian mixed-effects Bradley-Terry model. Error bars represent 95% confidence intervals. Statistical significance is indicated by asterisks (*$P < 0.05$, ***$P < 0.001$; Wald test). Right: Matrix of standardized logarithmic reaction times (Z-Log-RT) for pairwise comparisons, where darker colors indicate longer decision times and higher discrimination difficulty.

Fig. 2 Elastodynamic simulation of cutaneous shear wave propagation and stress distribution. a, Spatial distributions of peak shear stress in the xy-plane for representative modulation patterns (ULM_L, DLM_3, and LM_L), illustrating distinct energy concentration profiles. **b**, Spatiotemporal (x-t) diagrams of the signed shear stress along the modulation trajectory ($y = 0$), visualizing the constructive interference and wave propagation dynamics. **c**, Temporal waveforms of shear stress at the focal center during the steady-state phase (last 15 ms). **d**, Normalized lateral focusing profiles comparing the spatial resolution across all modulation strategies. The full width at half maximum (FWHM) is annotated for each pattern. **e**, Cross-sectional distribution of the root-mean-square (RMS) shear stress along the lateral axis ($y = 0$). **f**, Spectral analysis of the induced shear waves (log scale), highlighting the fundamental frequency (200 Hz) and harmonic components generated by different spatiotemporal dynamics.
